Lecture #2

Maxwell’s Equations

Outline

• Maxwell’s equations
• Physical Boundary conditions
• Parameter relations
• Preparing Maxwell’s equations for CEM
• The wave equation and its solutions
• Scaling properties of Maxwell’s equations
Maxwell’s Equations

Maxwell’s Equations

James Clerk Maxwell

Born June 13, 1831
Edinburgh, Scotland

Died November 5, 1879
Cambridge, England

Sign Conventions for Waves

To describe a wave propagating the positive z direction, we have two choices:

\[ E(z,t) = A \cos(\omega t - kz) \quad \text{Most common in engineering} \]

\[ E(z,t) = A \cos(-\omega t + kz) \quad \text{Most common science and physics} \]

Both are correct, but we must choose a convention and be consistent with it. For time-harmonic signals, this becomes

\[ E(z) = A \exp(-j kz) \quad \text{Negative sign convention} \]

\[ E(z) = A \exp(+j kz) \quad \text{Positive sign convention} \]

**Parameter Definitions**

- Electric Field Intensity, \( \vec{E} \) (V/m)
- Electric Flux Density, \( \vec{D} \) (C/m²)
- Magnetic Field Intensity, \( \vec{H} \) (A/m)
- Magnetic Flux Density, \( \vec{B} \) (Wb/m²)
- Electric Current Density, \( \vec{J} \) (A/m²)
- Volume Charge Density, \( \rho_s \) (C/m³)
- Permittivity, \( \varepsilon \) (F/m)
- Permeability, \( \mu \) (H/m)
- Electrical Conductivity, \( \sigma \) (S/m)

**Constants**

- \( \varepsilon_0 = 8.8541878176 \times 10^{-12} \) (F/m)
- \( \mu_0 = 4\pi \times 10^{-7} \) (H/m)
- \( \mu_0 = 1.2566370614 \times 10^{-7} \) (H/m)
- \( \eta = 12\pi \) (Ω)
- \( \eta = 376.7031346177 \) (Ω)
- \( c = 299,792,458 \) (m/s)

**Lorentz Force Law**

\( \vec{F} = q \vec{E} + q \vec{v} \times \vec{B} \)

**Sign Convention**

- \( e^\pm \) for propagation in the \( \pm z \) direction.
Lecture 2 Slide 7

Lorentz Force Law

One additional equation is needed to completely describe classical electromagnetism...

\[ \vec{F} = q\vec{E} + q\vec{v} \times \vec{B} \]

\[ \text{Electric Force} \quad \text{Magnetic Force} \]

Lecture 2 Slide 8

Alternate Forms of Maxwell’s Equations

Maxwell’s Equations with Gaussian Units

\[ \nabla \cdot \vec{D} = 4\pi \rho, \quad \nabla \times \vec{E} = \frac{1}{c_0^2} \frac{\partial \vec{B}}{\partial t} \]
\[ \nabla \cdot \vec{B} = 4\pi \mu, \quad \nabla \times \vec{H} = \frac{1}{c_0} \left( \frac{4\pi}{c_0^2} \vec{J} + \frac{\partial \vec{D}}{\partial t} \right) \]

Relativistic Maxwell’s Equations

\[ \partial_v \vec{E}^{\text{rel}} = \mu \vec{J} \]
\[ \partial_v \left( \epsilon \vec{E}^{\text{rel}} \right) = 0 \]
\[ \partial_v \vec{J} = \frac{\partial}{\partial t} \left( \epsilon \vec{E}^{\text{rel}} \right) + \nabla \times \vec{B} \]

Maxwell’s Equations in Moving Media

\[ \nabla \cdot \vec{D} = 4\pi \rho, \quad \nabla \times \vec{E} = \frac{1}{c_0^2} \frac{\partial \vec{B}}{\partial t} + \nabla \times \alpha \vec{B} \times \vec{v} \]
\[ \nabla \cdot \vec{B} = 4\pi \mu, \quad \nabla \times \vec{H} = \frac{1}{c_0} \left( \frac{4\pi}{c_0^2} \vec{J} + \frac{\partial \vec{D}}{\partial t} + \nabla \times \alpha \vec{D} \times \vec{v} \right) \]

\[ \alpha = \frac{\mu - 1}{\mu c} \]
Time-Harmonic Maxwell’s Equations

**Time-Domain**

\[ \nabla \cdot \vec{D} = \rho_v \]
\[ \nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t} \]
\[ \nabla \cdot \vec{B} = 0 \]
\[ \nabla \times \vec{H} = \vec{J} + \frac{\partial \vec{D}}{\partial t} \]

**Frequency-Domain (e^{jkz} convention)**

\[ \nabla \cdot \vec{D} = \rho_v \]
\[ \nabla \times \vec{E} = j \omega \vec{B} \]
\[ \nabla \cdot \vec{B} = 0 \]
\[ \nabla \times \vec{H} = \vec{J} - j \omega \vec{D} \]

**Frequency-Domain (e^{-jkz} convention)**

\[ \nabla \cdot \vec{D} = \rho_v \]
\[ \nabla \times \vec{E} = -j \omega \vec{B} \]
\[ \nabla \cdot \vec{B} = 0 \]
\[ \nabla \times \vec{H} = \vec{J} + j \omega \vec{D} \]

Gauss’s Law

\[ \nabla \cdot \vec{D} = \rho_v \]
\[ \nabla \cdot \vec{D} = \frac{\partial D_x}{\partial x} + \frac{\partial D_y}{\partial y} + \frac{\partial D_z}{\partial z} \]

Electric fields diverge from positive charges and converge on negative charges.

If there are no charges, electric fields must form loops.
**Gauss’s Law for Magnetism**

\[ \nabla \cdot \vec{B} = 0 \]

\[ \nabla \cdot \vec{B} = \frac{\partial B_x}{\partial x} + \frac{\partial B_y}{\partial y} + \frac{\partial B_z}{\partial z} \]

Magnetic fields always form loops.

**Consequence of Zero Divergence**

The divergence theorems force the \( \mathbf{D} \) and \( \mathbf{B} \) fields to be perpendicular to the propagation direction of a plane wave.

\[ \nabla \cdot \vec{D} = 0 \]

\[ \nabla \cdot (\vec{d} e^{-j\omega t}) = 0 \]

\[ -j \vec{k} \cdot \vec{d} = 0 \]

\[ \vec{k} \cdot \vec{d} = 0 \]

\[ \nabla \cdot \vec{B} = 0 \]

\[ \nabla \cdot (\vec{b} e^{-j\omega t}) = 0 \]

\[ -j \vec{k} \cdot \vec{b} = 0 \]

\[ \vec{k} \cdot \vec{b} = 0 \]
Ampere’s Law with Maxwell’s Correction

\[ \nabla \times \vec{H} = \vec{J} + \frac{\partial \vec{D}}{\partial t} \]

\[ \nabla \times \vec{H} = \left( \frac{\partial H_z}{\partial y} - \frac{\partial H_y}{\partial z} \right) \hat{a}_x + \left( \frac{\partial H_x}{\partial z} - \frac{\partial H_z}{\partial x} \right) \hat{a}_y + \left( \frac{\partial H_y}{\partial x} - \frac{\partial H_x}{\partial y} \right) \hat{a}_z \]

Circulating magnetic fields induce currents and/or time varying electric fields.

Currents and/or time varying electric fields induce circulating magnetic fields.

Faraday’s Law of Induction

\[ \nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t} \]

\[ \nabla \times \vec{E} = \left( \frac{\partial E_z}{\partial y} - \frac{\partial E_y}{\partial z} \right) \hat{a}_x + \left( \frac{\partial E_x}{\partial z} - \frac{\partial E_z}{\partial x} \right) \hat{a}_y + \left( \frac{\partial E_y}{\partial x} - \frac{\partial E_x}{\partial y} \right) \hat{a}_z \]

Circulating electric fields induce time varying magnetic fields.

Time varying magnetic fields induce circulating electric fields.
**Consequence of Curl Equations**

The curl equations predict electromagnetic waves!!

![Image](image1.png)

**The Constitutive Relations**

**Electric Response**

\[ \vec{D} = \varepsilon \vec{E} \]

- Electric field intensity (V/m)
- Initial electric “push.”
- Induced electric field.
- Electric energy in vacuum.
- Permittivity (F/m)
- Measure of how well a material stores electric energy.

- Electric flux density (C/m²)
- Pretends as if all electric energy is displaced charge.
- Includes electric energy in vacuum and matter.

**Magnetic Response**

\[ \vec{B} = \mu \vec{H} \]

- Magnetic field intensity (A/m)
- Initial magnetic “push.”
- Induced magnetic field.
- Magnetic energy in vacuum.
- Permeability (H/m)
- Measure of how well a material stores magnetic energy.

- Magnetic flux density (Wb/m²)
- Pretends as if all magnetic energy is tilted magnetic dipoles.
- Includes magnetic energy in vacuum and matter.
Material Classifications

Linear, isotropic and non-dispersive materials:
\[ \bar{D}(t) = \varepsilon \bar{E}(t) \]

Dispersive materials:
\[ \bar{D}(t) = \varepsilon(t) \ast \bar{E}(t) \]

Anisotropic materials:
\[ \bar{D}(t) = [\varepsilon] \bar{E}(t) \]

Nonlinear materials:
\[ D(t) = \varepsilon_0 \chi_e^{(1)} E(t) + \varepsilon_0 \chi_e^{(2)} E^2(t) + \varepsilon_0 \chi_e^{(3)} E^3(t) + \cdots \]

Types of Anisotropy

\[ \frac{\partial H_x}{\partial x} - \frac{\partial H_y}{\partial y} = J_z + \frac{\partial D_z}{\partial t} \]

Alternate Form of Maxwell’s Equations in Cartesian Coordinates

(1 of 2)

Alternate Curl Equations

\[ \nabla \times \vec{E} = \frac{\varepsilon_0}{\varepsilon} \frac{\partial \vec{B}}{\partial t} \]

\[ \left( \frac{\partial H_y}{\partial z} - \frac{\partial H_z}{\partial y} \right) \hat{a}_x + \left( \frac{\partial H_z}{\partial x} - \frac{\partial H_x}{\partial z} \right) \hat{a}_y + \left( \frac{\partial H_x}{\partial y} - \frac{\partial H_y}{\partial x} \right) \hat{a}_z = \left( \varepsilon_0 \frac{\partial E_x}{\partial t} + \varepsilon_0 \frac{\partial E_y}{\partial t} + \varepsilon_0 \frac{\partial E_z}{\partial t} \right) \hat{a}_x \]

\[ + \left( \varepsilon_0 \frac{\partial E_y}{\partial t} + \varepsilon_0 \frac{\partial E_z}{\partial t} + \varepsilon_0 \frac{\partial E_x}{\partial t} \right) \hat{a}_y \]

\[ + \left( \varepsilon_0 \frac{\partial E_z}{\partial t} + \varepsilon_0 \frac{\partial E_x}{\partial t} + \varepsilon_0 \frac{\partial E_y}{\partial t} \right) \hat{a}_z \]

\[ \frac{\partial H_y}{\partial y} - \frac{\partial H_z}{\partial z} = \varepsilon_0 \frac{\partial E_x}{\partial t} + \varepsilon_0 \frac{\partial E_y}{\partial t} + \varepsilon_0 \frac{\partial E_z}{\partial t} \]

\[ \frac{\partial H_z}{\partial z} - \frac{\partial H_x}{\partial x} = \varepsilon_0 \frac{\partial E_x}{\partial t} + \varepsilon_0 \frac{\partial E_y}{\partial t} + \varepsilon_0 \frac{\partial E_z}{\partial t} \]

\[ \frac{\partial H_x}{\partial x} - \frac{\partial H_y}{\partial y} = \varepsilon_0 \frac{\partial E_x}{\partial t} + \varepsilon_0 \frac{\partial E_y}{\partial t} + \varepsilon_0 \frac{\partial E_z}{\partial t} \]
Alternate Form of Maxwell's Equations in Cartesian Coordinates (2 of 2)

Alternate Curl Equations

\[ \nabla \times \vec{E} = -\mu \frac{\partial \vec{H}}{\partial t} \]

\[ \left( \frac{\partial E_x}{\partial y} - \frac{\partial E_y}{\partial z} \right) \hat{a}_x + \left( \frac{\partial E_y}{\partial z} - \frac{\partial E_z}{\partial x} \right) \hat{a}_y + \left( \frac{\partial E_z}{\partial x} - \frac{\partial E_x}{\partial y} \right) \hat{a}_z = -\left( \mu_x \frac{\partial H_x}{\partial t} + \mu_y \frac{\partial H_y}{\partial t} + \mu_z \frac{\partial H_z}{\partial t} \right) \hat{a}_x - \left( \mu_x \frac{\partial H_x}{\partial t} + \mu_y \frac{\partial H_y}{\partial t} + \mu_z \frac{\partial H_z}{\partial t} \right) \hat{a}_y - \left( \mu_x \frac{\partial H_x}{\partial t} + \mu_y \frac{\partial H_y}{\partial t} + \mu_z \frac{\partial H_z}{\partial t} \right) \hat{a}_z \]

Physical Boundary Conditions
Physical Boundary Conditions

### $\mu_1$ and $\varepsilon_1$

- Tangential components of $E$ and $H$ are continuous across an interface.
- $E$ and $H$ fields normal to the interface are discontinuous across an interface.
- Note: Normal components of $D$ and $B$ are continuous across the interface.
- Tangential components of the wave vector are continuous across an interface.

### $\mu_2$ and $\varepsilon_2$

- These are more complicated boundary conditions, physically and analytically.

Parameter Relations
The Relative Permittivity

The permittivity is a measure of how well a material stores electric energy. A circulating magnetic field induces an electric field at the center of the circulation in proportion to the permittivity.

\[ \nabla \times \vec{H} = \varepsilon \frac{\partial \vec{E}}{\partial t} \]

\[ \tilde{\varepsilon} = \varepsilon' - j\varepsilon'' \]

The dielectric constant of a material is its permittivity relative to the permittivity of free space.

\[ \varepsilon = \varepsilon_0 \varepsilon_r \]

\[ \varepsilon_0 = 8.854187817 \times 10^{-12} \text{ F/m} \]

\[ 1 \leq \varepsilon_r \leq \infty \]

\( \varepsilon_r \) is the relative permittivity or dielectric constant.
The Relative Permeability

The permeability is a measure of how well a material stores magnetic energy. A circulating electric field induces a magnetic field at the center of the circulation in proportion to the permeability.

\[ \nabla \times \vec{E} = -\mu \frac{\partial \vec{H}}{\partial t} \]

\[ \tilde{\mu} = \mu' - j \mu'' \]

The relative permeability of a material is its permeability relative to the permeability of free space.

\[ \mu = \mu_0 \mu_r \]

\[ \mu_0 = 1.256637061 \times 10^{-6} \text{ H/m} \]

\[ 1 \leq \mu_r \leq \infty \]

\[ \mu_r \text{ is the relative permeability} \]

Conductivity \( \sigma \)

Conductivity is the measure of a material’s ability to support electric current. This term is responsible for ohmic loss in materials.

It appears in Ampere’s Circuit Law.

\[ \nabla \times \vec{H} = \vec{J} + j \omega \vec{D} \]

The current density \( \vec{J} \) is related to conductivity and the electric field intensity through Ohm’s Law.

\[ \vec{J} = \sigma \vec{E} \]
**ε′-jε” Vs. ε and σ**

It is redundant to have a complex dielectric constant along with a conductivity term, although it happens. We should use either a complex dielectric constant or a real dielectric constant and a conductivity.

\[
\nabla \times \vec{H} = j\omega (\varepsilon' - j\varepsilon'') \vec{E} \\
\nabla \times \vec{H} = \sigma \vec{E} + j\omega \varepsilon \vec{E}
\]

\[
j\omega (\varepsilon' - j\varepsilon'') = \sigma + j\omega \varepsilon \\
\varepsilon' - j\varepsilon'' = \frac{\sigma}{j\omega} + \varepsilon \\
\varepsilon' = \varepsilon \\
\varepsilon'' = \frac{\sigma}{\omega}
\]

**Material Impedance**

The material impedance is the parameter which describes the balance between the electric and magnetic field amplitudes.

\[
\eta = \left| \frac{\vec{E}}{\vec{H}} \right|
\]

It is calculated from the permeability and permittivity of the material.

\[
\eta = \sqrt{\frac{\mu}{\varepsilon}} = \eta_0 \sqrt{\frac{\mu_r}{\varepsilon_r}}
\]

\[
\eta = |\eta| \angle \theta \quad \text{Phase between E and H}
\]

\[
\eta = \eta' + j\eta'' \quad \text{Amplitude between E and H}
\]

\[
\eta = \eta_0 = \text{free space impedance} = 376.73031346177 \ \Omega
\]

Impedance tells us that E and H are three orders of magnitude different.
The Complex Refractive Index

The permittivity and permeability appear in Maxwell’s equations so they are the most fundamental material properties. However, it is difficult to determine physical meaning from them in terms of how waves propagate (i.e. speed, loss, etc.). In this case, the refractive index is a more meaningful quantity.

\[ \tilde{n} = \sqrt{\mu_r \varepsilon_r} \]

In the frequency-domain, the refractive index is a complex quantity.

\[ \tilde{n} = n_o - j\kappa \]  
\( n_o \) is the ordinary refractive index. It quantifies how quickly a wave propagates.

\[ \kappa \] is the extinction coefficient. It quantifies loss and how quickly a wave decays.

* Note: when only the refractive index \( n \) is specified for a material, assume \( \mu = 1.0 \).

The Complex Propagation Constant, \( \gamma \)

The propagation constant is very close to the complex refractive index. It describes the speed and decay of a wave.

\[ E(z) = E_0 e^{-\gamma z} \]

The propagation constant has a real and imaginary part.

\[ \gamma = \alpha + j\beta \]  
\( \alpha \) is the attenuation coefficient. It quantifies how quickly the amplitude of a wave decays.

\( \beta \) is the propagation constant. It quantifies how quickly a wave accumulates phase.

It is related to the complex refractive index through

\[ \gamma = jk_0 \tilde{n} \]
The Absorption Coefficient, $\alpha$

The absorption coefficient describes how quickly the power in a wave decays.

$$P(z) = P_0 e^{-\alpha z}$$

WARNING: Notice the unfortunate reuse of the symbol $\alpha$ for two different things. This is easily confused!!

The attenuation coefficient and absorption coefficient are related through

$$\alpha_{\text{abs}} = 2\alpha_{\text{att}}$$

The absorption coefficient and extinction coefficient are related through

$$\alpha_{\text{abs}} = 2k_0 \kappa$$

Loss Tangent

Sometimes material loss is given in terms of a “loss tangent.”

$$\tan \delta = \frac{\varepsilon''}{\varepsilon'} = \frac{\sigma}{\omega \varepsilon}$$

Recall that interpreting wave properties (velocity and loss) is not intuitive using just the complex dielectric function. To do this, we preferred the complex refractive index.

It turns out that the loss tangent and the extinction coefficient are essentially the same.

$$\delta = \frac{2\kappa}{n} = \frac{\alpha_{\text{abs}}}{k_0 n}$$

It is called a loss tangent because it is the angle in the complex plane formed between the resistive component and the reactive component of the electromagnetic field.
\[ \omega \text{ versus } f \]

\( \omega \) is the angular frequency measured in radians per second. It relates more directly to phase and \( k \). Think \( \cos(\omega t) \).

\( f \) is the ordinary frequency measured in cycles per second. It relates more directly to time. Think \( \cos(2\pi ft) \) and \( \tau = 1/f \).

\[ \omega = 2\pi f \]

\[ \text{Wavelength and Frequency} \]

The frequency \( f \) and free space wavelength \( \lambda_0 \) are related through

\[ c_0 = f \lambda_0 \quad c_0 = 299792458 \text{ m/s} = \text{speed of light in vacuum} \]

Inside a material, the wave slows down according to the refractive index as follows.

\[ v = \frac{c_0}{n} \]
### Summary of Parameter Relations

**Permittivity**

\[ \varepsilon = \varepsilon_0 \varepsilon_r \]

\[ \varepsilon_0 = 8.854187817 \times 10^{-12} \text{ F/m} \]

**Permeability**

\[ \mu = \mu_0 \mu_r \]

\[ \mu_0 = 1.256637061 \times 10^{-6} \text{ H/m} \]

**Refractive Index**

\[ n = \sqrt{\mu \varepsilon} \]

\[ \eta = \eta_0 \sqrt{\mu / \varepsilon} \]

\[ \eta_0 = \sqrt{\mu_0 / \varepsilon_0} = 376.73031346177 \text{ \Omega} \]

**Impedance**

\[ \eta = \frac{\varepsilon \mu}{\varepsilon_0 \mu_0} \]

\[ \eta_0 = \sqrt{\mu_0 / \varepsilon_0} = 376.73031346177 \text{ \Omega} \]

**Wave Velocity**

\[ v = \frac{c_0}{n} \]

\[ c_0 = 299792458 \text{ m/s} \]

**Wave Number**

\[ k = \frac{2\pi}{\lambda} \]

Preparing Maxwell’s Equations for CEM

Simplifying Maxwell’s Equations

1. Assume no charges or current sources: $\rho = 0, \ J = 0$

\[
\nabla \cdot \vec{B} = 0 \quad \nabla \times \vec{H} = \varepsilon \frac{\partial \vec{E}}{\partial t} \quad \vec{D}(t) = \left[ \varepsilon(t) \right] \vec{E}(t)
\]

\[
\nabla \cdot \vec{D} = 0 \quad \nabla \times \vec{E} = -\varepsilon \frac{\partial \vec{B}}{\partial t} \quad \vec{B}(t) = \left[ \mu(t) \right] \vec{H}(t)
\]

2. Transform Maxwell’s equations to frequency-domain:

\[
\nabla \cdot \vec{B} = 0 \quad \nabla \times \vec{H} = j\omega \vec{D} \quad \vec{D} = \left[ \varepsilon \right] \vec{E}
\]

\[
\nabla \cdot \vec{D} = 0 \quad \nabla \times \vec{E} = -j\omega \vec{B} \quad \vec{B} = \left[ \mu \right] \vec{H}
\]

3. Substitute constitutive relations into Maxwell’s equations:

\[
\nabla \cdot \left( \left[ \mu \right] \vec{H} \right) = 0 \quad \nabla \times \vec{H} = j\omega \left[ \varepsilon \right] \vec{E}
\]

\[
\nabla \cdot \left( \left[ \varepsilon \right] \vec{E} \right) = 0 \quad \nabla \times \vec{E} = -j\omega \left[ \mu \right] \vec{H}
\]

Note: We have chose to proceed with the negative sign convention.

Note: It is useful to retain $\mu$ and $\varepsilon$ and not replace them with refractive index $n$.  Convolution becomes simple multiplication.
Isotropic Materials

For anisotropic materials, the permittivity and permeability terms are tensor quantities.

\[
\begin{bmatrix}
\varepsilon_{xx} & \varepsilon_{xy} & \varepsilon_{xz} \\
\varepsilon_{yx} & \varepsilon_{yy} & \varepsilon_{yz} \\
\varepsilon_{zx} & \varepsilon_{zy} & \varepsilon_{zz}
\end{bmatrix}
\begin{bmatrix}
\mu_{xx} & \mu_{xy} & \mu_{xz} \\
\mu_{yx} & \mu_{yy} & \mu_{yz} \\
\mu_{zx} & \mu_{zy} & \mu_{zz}
\end{bmatrix}
\]

For isotropic materials, the tensors reduce to a single scalar quantity.

\[
\begin{bmatrix}
\varepsilon & 0 & 0 \\
0 & \varepsilon & 0 \\
0 & 0 & \varepsilon
\end{bmatrix} = \varepsilon \\
\begin{bmatrix}
\mu & 0 & 0 \\
0 & \mu & 0 \\
0 & 0 & \mu
\end{bmatrix} = \mu
\]

Maxwell’s equations can then be written as

\[
\nabla \cdot (\mu \hat{H}) = 0 \\
\nabla \times \hat{H} = j \omega \varepsilon \hat{E}
\]

\[
\nabla \cdot (\varepsilon \hat{E}) = 0 \\
\nabla \times \hat{E} = -j \omega \mu \hat{H}
\]

\( \varepsilon \) and \( \mu \) dropped from these equations because they are constants and do not vary spatially.

Expand Maxwell’s Equations

Divergence Equations

\[
\nabla \cdot (\mu \hat{H}) = 0 \\
\frac{\partial (\mu \hat{H})_x}{\partial x} + \frac{\partial (\mu \hat{H})_y}{\partial y} + \frac{\partial (\mu \hat{H})_z}{\partial z} = 0
\]

\[
\nabla \cdot (\varepsilon \hat{E}) = 0 \\
\frac{\partial (\varepsilon \hat{E})_x}{\partial x} + \frac{\partial (\varepsilon \hat{E})_y}{\partial y} + \frac{\partial (\varepsilon \hat{E})_z}{\partial z} = 0
\]

Curl Equations

\[
\nabla \times \hat{H} = j \omega \varepsilon \hat{E} \\
\frac{\partial H_x}{\partial y} - \frac{\partial H_y}{\partial z} = j \omega \varepsilon E_x \\
\frac{\partial H_z}{\partial x} - \frac{\partial H_x}{\partial y} = j \omega \varepsilon E_y \\
\frac{\partial H_y}{\partial z} - \frac{\partial H_z}{\partial x} = j \omega \varepsilon E_z
\]

\[
\nabla \times \hat{E} = -j \omega \mu \hat{H} \\
\frac{\partial E_x}{\partial y} - \frac{\partial E_y}{\partial z} = -j \omega \mu H_x \\
\frac{\partial E_z}{\partial x} - \frac{\partial E_x}{\partial y} = -j \omega \mu H_y \\
\frac{\partial E_x}{\partial z} - \frac{\partial E_z}{\partial x} = -j \omega \mu H_z
\]
Normalize the Magnetic Field

**Standard form of “Maxwell’s Curl Equations”**

\[ \nabla \times \vec{E} = -j \omega \mu_0 \mu_r \vec{H} \quad \nabla \times \vec{H} = j \omega \varepsilon_0 \varepsilon_r \vec{E} \]

**Normalized Magnetic Field**

\[ \frac{|\vec{E}|}{|\vec{H}|} \approx \frac{377}{n} \quad \vec{H} = -j \sqrt{\frac{\mu_0}{\varepsilon_0}} \vec{H} \]

**Note:**

- Eliminates \( j \omega \)
- No sign inconsistency
- Just have \( k_0 \)

- Equalizes \( E \) and \( H \) amplitudes

**Normalized Maxwell’s Equations**

\[ \nabla \times \vec{E} = k_0 \mu_r \vec{H} \quad \nabla \times \vec{H} = k_0 \varepsilon_r \vec{E} \]

---

Starting Point for Most CEM

We arrive at the following set of equations that are the same regardless of the sign convention used.

\[ \begin{align*}
\frac{\partial E_y}{\partial z} - \frac{\partial E_z}{\partial y} &= k_0 \mu_{xy} \tilde{H}_x \\
\frac{\partial E_z}{\partial z} - \frac{\partial E_y}{\partial x} &= k_0 \mu_{yx} \tilde{H}_y \\
\frac{\partial E_x}{\partial z} - \frac{\partial E_z}{\partial y} &= k_0 \mu_{zz} \tilde{H}_z \\
\frac{\partial H_x}{\partial y} - \frac{\partial H_y}{\partial x} &= k_0 \varepsilon_{xy} E_x \\
\frac{\partial H_y}{\partial z} - \frac{\partial H_z}{\partial x} &= k_0 \varepsilon_{yz} E_y \\
\frac{\partial H_z}{\partial z} - \frac{\partial H_x}{\partial y} &= k_0 \varepsilon_{zz} E_z 
\end{align*} \]

The manner in which the magnetic field is normalized does depend on the sign convention chosen.

\[ \frac{z}{H} = \begin{cases} -j \eta_0 \tilde{H} & \text{negative sign convnetion} \\ +j \eta_0 \tilde{H} & \text{positive sign convnetion} \end{cases} \]
The Wave Equation and Its Solutions

Derivation of the Wave Equation

We start with Maxwell’s curl equations.

\[ \nabla \times \vec{E} = -j \omega \mu_0 \mu_r \vec{H} \quad \text{Eq. (1)} \]
\[ \nabla \times \vec{H} = j \omega \varepsilon_0 \varepsilon_r \vec{E} \quad \text{Eq. (2)} \]

Equation (1) is solved for the magnetic field.

\[ \vec{H} = \frac{j}{\omega \mu_0 \mu_r} (\nabla \times \vec{E}) \quad \text{Eq. (3)} \]

Equation (3) is substituted into Eq. (2).

\[ \nabla \times \left[ \frac{j}{\omega \mu_0 \mu_r} (\nabla \times \vec{E}) \right] = j \omega \varepsilon_0 \varepsilon_r \vec{E} \]

\[ \nabla \times \left[ \frac{1}{\mu_r} (\nabla \times \vec{E}) \right] = k_0^2 \varepsilon_r \vec{E} \]
Two Different Wave Equations

We can derive a wave equation for both $E$ and $H$.

\[
\nabla \times \varepsilon_{r}^{-1} \nabla \times \vec{E} = k_{0}^{2} \varepsilon_{r} \vec{E} \\
\nabla \times \varepsilon_{r}^{-1} \nabla \times \vec{H} = k_{0}^{2} \mu_{r} \vec{H}
\]

It is not actually possible to simplify these equations further without making an approximation. Assuming a linear homogeneous isotropic (LHI) material, the wave equations reduce to

\[
\nabla \times \nabla \times \vec{E} = k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{E} \\
\nabla \times \nabla \times \vec{H} = k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{H}
\]

\[
\nabla \left( \nabla \cdot \vec{E} \right) - \nabla^{2} \vec{E} = k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{E} \\
\nabla \left( \nabla \cdot \vec{H} \right) - \nabla^{2} \vec{H} = k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{H}
\]

\[
\nabla^{2} \vec{E} + k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{E} = 0 \\
\nabla^{2} \vec{H} + k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{H} = 0
\]

We see that these equations will have the same solution since it is the same differential equation! So, we only have to solve one of them.

Plane Wave Solution in Homogeneous Media

Given the wave equation in an LHI material,

\[
\nabla^{2} \vec{E} + k_{0}^{2} \mu_{r} \varepsilon_{r} \vec{E} = 0
\]

The solution is a plane wave.

\[
\vec{E} (\vec{r}) = \vec{E}_{0} \exp \left( \pm jk \cdot \vec{r} \right) \\
\vec{H} (\vec{r}) = \vec{H}_{0} \exp \left( \pm jk \cdot \vec{r} \right)
\]
Amplitude Relation

Given plane wave functions of the form

\[ \vec{E}(\vec{r}) = \vec{E}_0 \exp(-j\vec{k} \cdot \vec{r}) \]
\[ \vec{H}(\vec{r}) = \vec{H}_0 \exp(-j\vec{k} \cdot \vec{r}) \]

The amplitudes are related through Maxwell’s equations.

\[ \nabla \times \vec{E} = -j\omega \mu_0 \mu_r \vec{H} \]
\[ \nabla \times (\vec{E}_0 e^{-j\vec{k} \cdot \vec{r}}) = -j\omega \mu_0 \mu_r (\vec{H}_0 e^{-j\vec{k} \cdot \vec{r}}) \]
\[ -j(\vec{k} \times \vec{E}_0) e^{-j\vec{k} \cdot \vec{r}} = -j\omega \mu_0 \mu_r \vec{H}_0 e^{-j\vec{k} \cdot \vec{r}} \]
\[ \vec{k} \times \vec{E}_0 = \omega \mu_0 \mu_r \vec{H}_0 \]

IMPORTANT: Plane Waves are of Infinite Extent

Many times we just draw rays or sometime rays with perpendicular lines to represent the wave fronts.

Unfortunately, this suggests the wave is confined spatially. In reality, plane waves are of infinite extent. Think more this way...
Solving the Wave Equation as a Scattering Problem

Scattering problems cast the wave equation into the following matrix form.

\[ \nabla \times \mu^{-1} \nabla \times \vec{E} - k_0^2 \varepsilon \varepsilon_r \vec{E} = g \]

\[ Ax = b \]

A source \( b \) is needed

• Only one solution exists

\[ A = (\nabla \times \mu^{-1} \nabla \times -k_0^2 \varepsilon \varepsilon_r) \]

\[ x = \vec{E} \]

\[ b = g \]

Solving the Wave Equation as an Eigen-Value Problem

The wave equation can also be solved as an eigen-value problem. This approach is used when “modes” are being calculated.

\[ \nabla \times \mu^{-1} \nabla \times \vec{E} = k_0^2 \varepsilon \varepsilon_r \vec{E} \]

\[ Ax = \lambda B x \]

\[ A = \nabla \times \mu^{-1} \nabla \times \]

\[ B = \varepsilon \varepsilon_r \]

• No source is needed

• Multiple solutions exist

\[ x = \vec{E} \]

\[ \lambda = k_0^2 \]
### Wave Equation Vs. Maxwell’s Equations

<table>
<thead>
<tr>
<th>Wave Equation</th>
<th>Maxwell’s Equations</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>( \nabla^2 \vec{H} + k_0^2 \mu_r \epsilon_r \vec{H} = 0 )</td>
<td></td>
</tr>
</tbody>
</table>

Today, it is rare to see the wave equations solved in this form because it leads to spurious solutions.

The “fixes” to the spurious solutions problem are incorporated into Maxwell’s equations before a wave equation is derived.

### Scaling Properties in Maxwell’s Equations

Scaling Properties in Maxwell’s Equations
Scaling Properties of Maxwell’s Equations

There is no fundamental length scale in Maxwell’s equations.

Devices may be scaled to operate at different frequencies just by scaling the mechanical dimensions or material properties in proportion to the change in frequency.

This assumes it is physically possible to scale systems in this manner. In practice, building larger or smaller features may not be practical. Further, the properties of the materials may be different at the new operating frequency.

Scaling Dimensions

We start with the wave equation and write the parameters dependence on position explicitly.

\[ \nabla \times \left( \frac{1}{\mu_r(\hat{r})} \nabla \times \vec{E}(\hat{r}) \right) = \omega^2 \mu_0 \varepsilon_0 \cdot \varepsilon_r(\hat{r}) \cdot \vec{E}(\hat{r}) \]

Next, we scale the dimensions by a factor \( a \).

\[ (a \nabla) \times \left( \frac{1}{\mu_r(\hat{r}/a)} \right) \times \vec{E}(\hat{r}/a) = \omega^2 \mu_0 \varepsilon_0 \cdot \varepsilon_r(\hat{r}/a) \cdot \vec{E}(\hat{r}/a) \]

The scale factors multiplying the \( \nabla \) operators are moved to multiply the frequency term.

\[ \nabla \times \left( \frac{1}{\mu_r(\hat{r}')} \right) \nabla \times \vec{E}(\hat{r}') = \left( \frac{\omega}{a} \right)^2 \mu_0 \varepsilon_0 \cdot \varepsilon_r(\hat{r}') \cdot \vec{E}(\hat{r}') \quad \hat{r}' = \frac{\hat{r}}{a} \]

The effect of scaling the dimensions is just a shift in frequency.
Visualization of Size Scaling

\[ a = 1.0 \]

\[ f_c = 500 \text{ MHz} \]

\[ a = 0.5 \]

\[ f_c = 1000 \text{ MHz} \]

Scaling \( \mu \) and \( \varepsilon \)

We apply separate scaling factors to \( \mu \) and \( \varepsilon \).

\[ \nabla \times \frac{1}{(a_r \mu_r)} \nabla \times \vec{E} = \omega \varepsilon_0 \mu_0 \varepsilon_r (a_r \varepsilon_r) \cdot \vec{E} \]

The scale factors are moved to multiply the frequency term.

\[ \nabla \times \frac{1}{\mu_r} \nabla \times \vec{E} = (\omega \sqrt{a_r \mu_r})^2 \mu_0 \varepsilon_0 \cdot \varepsilon_r \cdot \vec{E} \]

The effect of scaling the material properties is just a shift in frequency.
